Thymomas alter the T-cell subset composition in the blood: a potential mechanism for thymoma-associated autoimmune disease

Viola Hoffacker, Anja Schultz, James J. Tiesinga, Ralf Gold, Berthold Schalke, Wilfred Nix, Reinhard Kiefer, Hans Konrad Müller-Hermelink, and Alexander Marx

Thymomas are the only tumors that are proven to generate mature T cells from immature precursors. It is unknown, however, whether intratumorous thymopoiesis has an impact on the peripheral T-cell pool and might thus be related to the high frequency of thymoma-associated myasthenia gravis. This study shows, using fluorescence-activated cell sorting-based analyses and T-cell proliferation assays, that thymopoiesis and T-cell function in thymomas correspond with immunologic alterations in the blood. Specifically, the proportion of circulating

CD45RA⁺CD8⁺ T cells is significantly increased in patients with thymoma compared with normal controls, in accordance with intratumorous T-cell development that is abnormally skewed toward the CD8⁺ phenotype. Moreover, it is primarily the proportion of circulating CD45RA⁺CD8⁺ T cells that decreases after thymectomy. The results also demonstrate that T cells reactive toward recombinant autoantigens are distributed equally between thymomas and blood, whereas T-cell responses to foreign antigen (ie, tetanus toxoid) are seen only

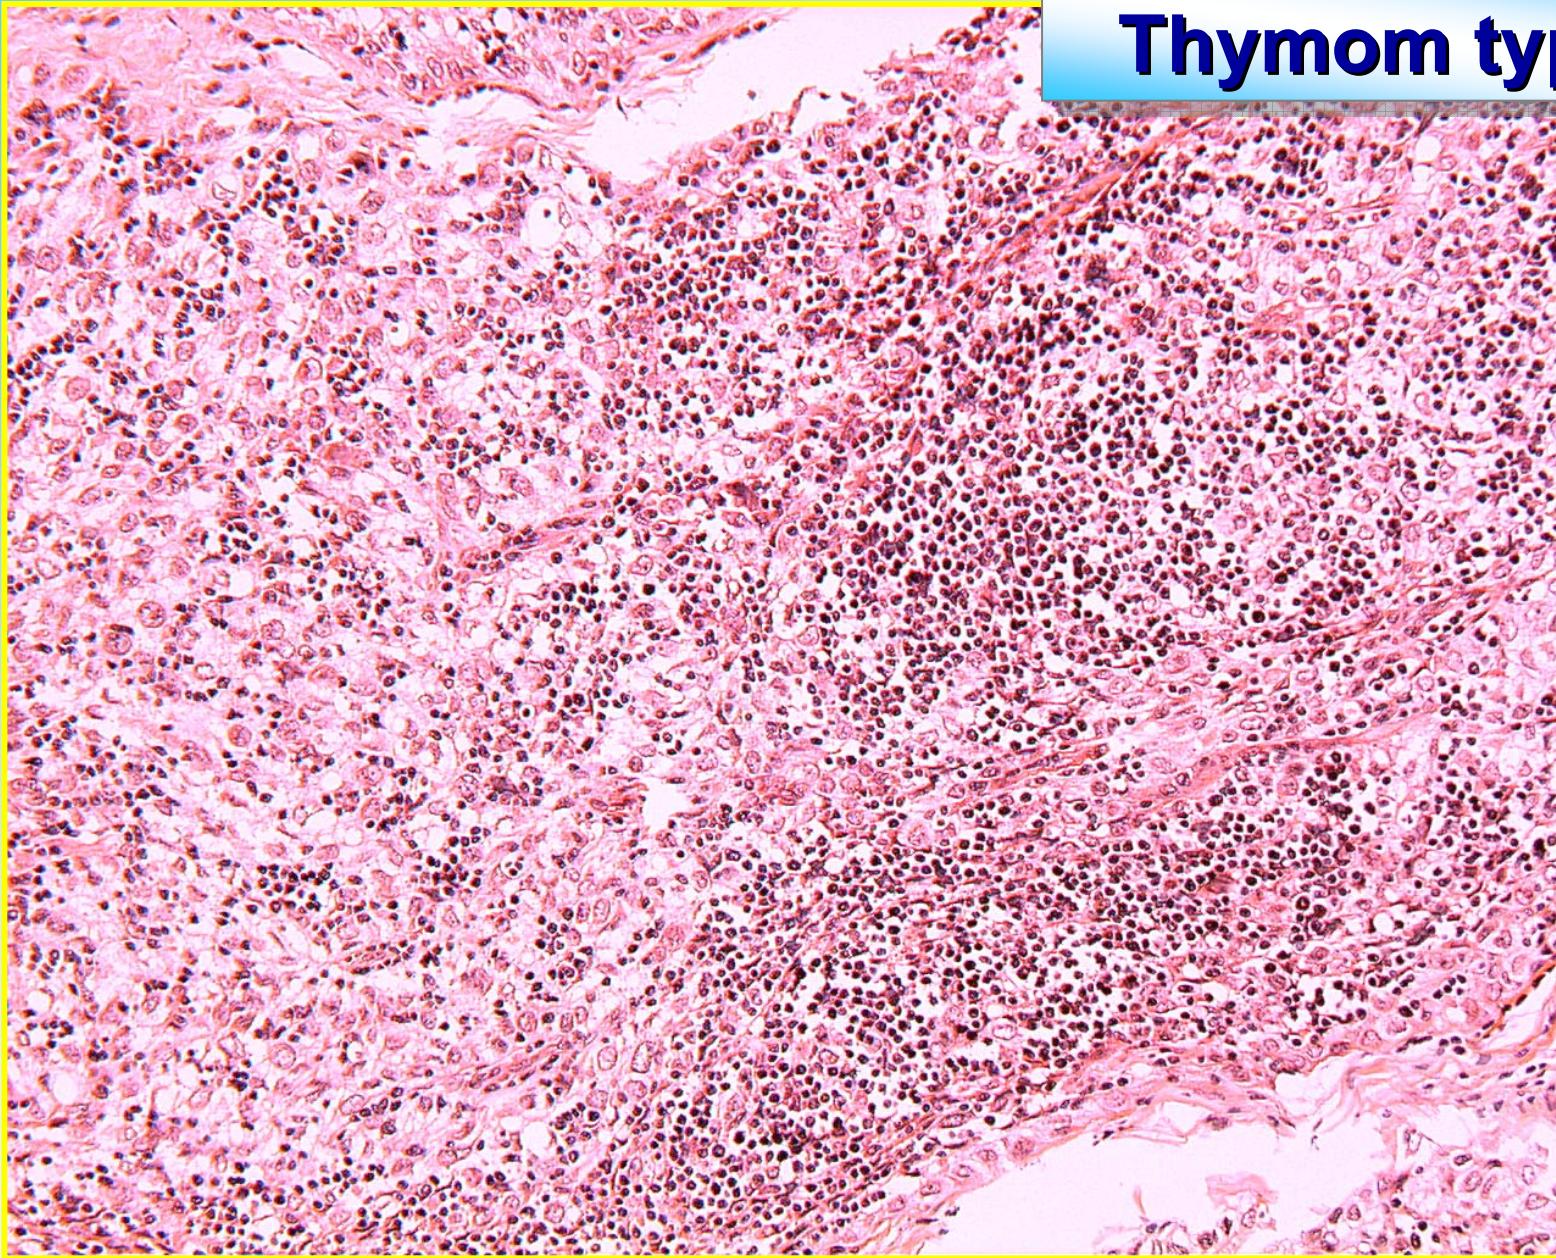

among circulating T cells and not among thymoma-derived T cells. These functional studies support the hypothesis that thymopoiesis occurring within thymomas alters the peripheral T-cell repertoire. Because many thymomas are enriched with autoantigen-specific T cells, a disturbance of circulating T-cell subset composition by export of intratumorous T cells may contribute to paraneoplastic autoimmune disease arising in patients with thymoma. Závěr

Lymfocyty v infiltrátech u MG:

- se liší od lymfocytů polymyositidy
- jsou tvořeny převážně CD45RA+CD8+ T lymf.
- pravděpodobně generovány thymomy bohatými na lymfocyty (typ B a AB)

CD45RA+ CD8+ lymfocyty → THYMOM
